None Surveyed Addresses 'Intelligent Design' on Tests

Many States Include Evolution Questions on Assessments

BY SEAN CAVANAGH

State science tests differ greatly in what they expect students to know about evolution, with some asking no questions about the theory and others including more than a dozen items related to it, an *Education Week* review has found.

Responses from more than 20 states to a survey on high school science assessments show that the vast majority of those states include at least one question that specifically refers to the term "evolution." Just three states responding—Alabama, Ohio, and South Dakota—indicated that their exams offered no questions using that word.

The theory of evolution, pioneered most famously by Charles Darwin, posits that humans and other living creatures have descended from common ancestors over time through a process of random mutation and natural selection. It is widely considered to be a pillar of modern biology. Over the past year, however, public education has been roiled by high-profile disputes over whether schools should subject evolution to greater criticism or promote purported alternative explanations for life's development, such as "intelligent design."

What is tested is typically what is taught, research shows. And all states will have to give science tests to comply with the federal No Child Left Behind Act beginning in the 2007-08 school year.

No states surveyed by *Education Week* said their high school science assessments include questions about intelligent design, the idea that an unnamed force may have guided life's development, or the biblically based belief known as creationism. The vast majority of scientists maintain that those concepts should not be considered science.

Similarly, none of the states surveyed said its statewide exams asked students about alleged weaknesses in evolution, or criticism of the theory, an approach that has been pushed by elected officials and interest groups around the country.

"I would have been very disappointed" if alternatives had shown up on tests, said Senta Raizen, the director of the National Center for Improving Science Education, in Arlington, Va. "Science is based on observations concerning natural phenomena. Belief systems do not. They may be legitimate for people who hold those beliefs, but they're not science."

> *"It's impossible to put an absolute number on ... the right number of questions to ask about evolution."*
>
> **Meryl Bertenthal**
> *National Research Council*

Ms. Raizen recently co-chaired a committee that directed the revision of the blueprint for the science portion of the National Assessment of Education Progress, perhaps the most closely scrutinized exam in the country, which influences many state assessments.

For its review, *Education Week* sent a list of questions to 29 states that, as of last school year, reported that they had science tests at the elementary, middle, and high school levels that were aligned with their state standards. The review focused on high school exams, the level at which evolution is typically taught in the greatest depth.

Of the 22 states that responded to the survey, 17 indicated they had at least one question that specifically mentioned evolution on the most recent exam, three states said they had none; one state, Kentucky, declined to answer the question; and another, Tennessee, said it was unlikely the term showed up in a question.

States tend to be protective of testing materials, mostly to ensure that the process remains tamper-proof. Thus, some states declined to say how many test items were connected to evolution.

Of those states that provided specifics, the number of questions on their high school science assessments that cited "evolution" as it pertains to biological changes in species ranged from zero to seven.

When asked how many questions related to evolution generally, without mentioning the word, some state officials said their tests included no such items, while others, such as New York and Utah, said they had as many as a dozen questions on the topic.

Test Deadlines Coming

In some ways, the contrasting approaches on evolution reflect different approaches in science testing overall.

Some of the states with the greatest number of evolution-related items give subject-specific tests in biology. Likewise, states with fewer of those questions test students across a broad range of scientific fields, such as physics and chemistry.

In addition, the total number of test questions varies from a low of 30 to a high of 180. Half the states surveyed said they use only multiple-choice items.

States are facing new pressure to test students in science. The No Child Left Behind law requires states to have science as-

Evolution Theory Well Represented In Leading High School Textbooks

BY SEAN CAVANAGH

Textbooks—teachers' road maps through the curriculum—generally do a respectable job of covering evolution, according to experts who have reviewed the books, though the thick volumes tend to be weaker in describing the theory's relevance across the many areas of science.

Leading textbooks strongly present major points on evolution, the experts say, despite being jammed with information to comply with the academic standards of so many different states—a concern across many subjects.

"If you look at the major textbooks on the market, they all have one, two, or three chapters on evolution," said Rodger W. Bybee, the executive director of the Biological Sciences Curriculum Study organization, in Colorado Springs, Colo., which develops textbooks and other instructional materials.

Despite scientists' concerns about the recent resurgence of criticism over the teaching of evolution, Mr. Bybee believes textbooks have, in fact, "strengthened empirical arguments" in presenting the theory in recent years, in response to critics' attempts to find holes in it. He expects those efforts in the coverage of evolution to continue.

A 2000 study by the American Association for the Advancement of Science in Washington found that high school biology books were strong in presenting basic facts on evolution and other major scientific concepts. But those facts were too often presented in isolation, that analysis found, rather than in ways that described evolution's influence throughout science.

"Kids need to understand why the scientific community supports evolution, and why it's important," said Jo Ellen Roseman, who directed the study and is also the director of Project 2061, an AAAS venture to improve learning in science, mathematics, and technology.

She attributed textbooks' weaknesses in coherence partly to the tendency of the authors—primarily college professors—to gloss over connections that seem obvious to them, but might not be to precollegiate students.

Sticking to Science?

Publishers and other textbook experts say major science books avoid discussing "intelligent design," a purported alternative to the theory of evolution, because the mainstream scientific community does not regard it as legitimate science. Yet one widely used textbook, Glencoe's 2004 edition of *Biology: The Dynamics of Life*, describes intelligent design and other views in a section titled "Biology and Society." The concept is described as a belief, not a scientific theory.

April Hattori, a spokeswoman for the Glencoe/McGraw-Hill, a division of the New York City-based McGraw-Hill Education, said the book makes no other references to intelligent design. Overall, it treats evolution as a "unifying concept" in science, she said, which the publisher recognizes is backed by the vast majority of scientists.

At the same time, some private schools have shown an increased interest in science textbooks that discuss either creationism or intelligent design, said Derek J. Keenan, a vice president of the Association of Christian Schools International, in Colorado Springs. His organization represents 3,700 U.S.-based religious schools, many of which use Christian-themed science texts alongside those favored by the mainstream scientific community. Those schools, he said, often seek out texts through Christian-oriented publishers, such as A Beka Book, in Pensacola, Fla.

A Close Reading

Textbooks have come under inspection in a closely watched federal lawsuit on the Dover, Pa., school board's decision last year to require students to be exposed to intelligent design. Sixty copies of a pro-intelligent-design textbook, *Of Pandas and People*, were anonymously donated to a district library.

Part of the controversy in Dover stemmed from board members' objections to approving the prominent Prentice Hall textbook *Biology*, for use in the district. That book, which gives a broad treatment to evolution, is written by Kenneth R. Miller, a Brown University biology professor, and Joseph S. Levine, a longtime science writer. During the trial, Mr. Miller was questioned by a school board lawyer about a heading on one section of the book titled "Strengths and Weaknesses of Evolutionary Theory."

Mr. Miller testified that the authors added that wording to conform with Texas state standards, which call for students to critique various scientific theories and hypotheses. The Dover policy says students should be exposed to "gaps/problems" in evolution; the language in Mr. Miller's book, the lawyer implied, seemed to justify such criticism.

The professor, however, said the headline was taken out of context. In-

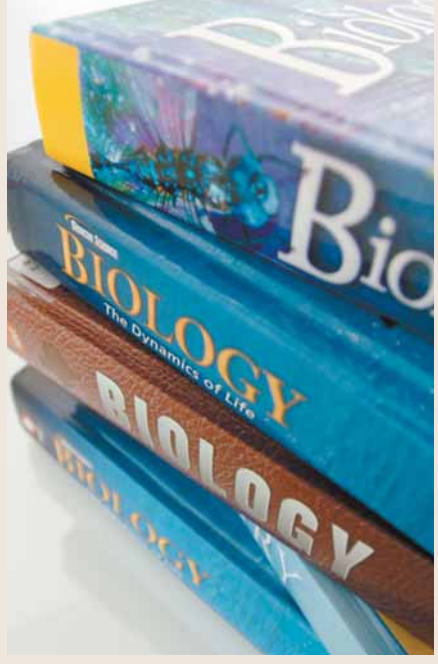

Photo illustration by Sevans/Education Week

In response to attacks on evolution, some textbook publishers have "strengthened empirical arguments" in their presentations of the theory in recent years, says one expert.

telligent-design advocates, he said in an interview, "will try to take that [language] and make something out of it." Virtually any textbook discussion of evolution, he noted, could be scrutinized in the same way.

Mr. Miller has heard criticism that one of his previous biology texts was long on evolution facts and short on coherence across subjects. Not so with *Biology*, he said, which tries to make those connections. In fact, the author joked that a Dover school board member's complaint that his book was "laced with Darwinism" could aptly describe his work.

"That," Mr. Miller said, "should be a quote on the back cover of my book."

State Lineup

Twenty-two states responded to an *Education Week* survey about the extent to which they test students' knowledge of evolution on high school science tests.

Alabama	Louisiana	South Carolina
California	Maryland	South Dakota
Connecticut	Mississippi	Tennessee
Delaware	Michigan	Texas
Georgia	New York	Utah
Kansas	North Carolina	Virginia
Kentucky	Ohio	
Illinois	Oregon	

SOURCE: *Education Week*

Different Takes

State and federal officials take a number of approaches in measuring students' knowledge of evolution. Some, for example, specifically cite the term "evolution," while others say they don't have questions that mention the word.

NAEP: 12th grade science test, sample question, 2000

Which of the following is NOT a part of Darwin's theory of evolution by natural selection?

A) Individuals in a population vary in many ways.
B) Some individuals possess features that enable them to survive better than individuals lacking those features.
C) More offspring are produced than can generally survive.
D) Changes in an individual's genetic material are usually harmful.

Alabama: Sample question, blueprint for state science test

Which of these is NOT an inherited trait that could help a species survive over time?

A) the shape of a finch's beak
B) the thickness of a bear's fur
C) a rabbit's instinct for avoiding predators
D) a human's resistance to disease by vaccination

(Correct answers are in bold.)

sessments in place at three grade levels—3-5, 6-9, and 10-12—by the end of the 2007-08 academic year, and to have standards in those subjects in place by this school year. According to a recent survey by the Council of Chief State School Officers, 42 states have science tests in place at the three levels, though not all are aligned with their standards.

Experts on science testing were not surprised by the broad differences in how states treat evolution. Those disparities could be attributed not only to the different ways in which exams are structured, they said, but also to the dissimilar ways in which state standards cover the theory.

"It's impossible to put an absolute number on what is the right number of questions to include about evolution," said Meryl Bertenthal, a former program officer at the congressionally chartered National Research Council, who has studied state science testing. "The emphasis and the depth [will be] similar to the state standards. … You're not likely to see questions that are not aligned with the standards."

A related *Education Week* analysis, published last month, showed that state standards documents vary greatly in their coverage of evolution, with many ignoring core concepts and evidence connected to the theory. *(See Education Week, Nov. 9, 2005.)*

Alabama's high school science assessment, which covers many science topics, does not include the term evolution, according to state officials' survey responses. Yet references to the theory are found in underlying language throughout the state's standards. The exam, however, is based on specific items in the standards that are highlighted as central concepts, said Gloria Turner, the state's director of assessment, and evolution is not one of them.

"We assess the content standards as they are written," she said.

'Can't Cover Everything'

In the past year, efforts to promote alternatives to evolution, or raise questions about its teaching, have played out in more than 30 states, according to the Oakland, Calif.-based National Center for Science Education, which monitors those fights.

One of the most visible battles has played out in the 3,600-student Dover, Pa., district, where the school board in 2004 approved a policy requiring that students be introduced to intelligent design. A federal lawsuit on the policy awaits a judge's ruling. (*See Education Week, Nov. 16, 2005.*)

Another equally visible fight occurred in Kansas, where state school board members last month included more criticism of evolution in state science standards.

The effect of those changes is unclear. Kansas' high school science test usually has four to six questions on evolution, out of 60 overall, and only those items would likely be affected, if state board members decided to revise their exam to reflect the new standards, said Alexa Posny, the state's deputy education commissioner for learning services.

All questions on Kansas' test, next administered in 2008, are multiple-choice. Ms. Posny was not sure how state officials might structure a multiple-choice question about criticism of evolution. "It would be a challenge," she said.

South Dakota also does not mention evolution specifically on its high school test, though officials said two questions related to the concept more generally. That state, however, is in the process of developing a new test to meet requirements of the NCLB law, said Gay Pickner, South Dakota's director of assessment. She did not know if the new test would include questions on evolution.

No questions on Ohio's 38-question science assessment, administered this past spring, referred to biological evolution, state officials said. That test is based on Ohio's state standards, which were revised in 2002 after an extended debate, to encourage critical analysis of evolution and broad coverage of the theory overall.

Deborah Owens Fink, an Ohio state school board member who supported those standards, was surprised that the concept did not appear on the state test. But she and other state officials noted that an original bank of potential questions included several evolution items. Those queries were eventually pared down to include randomly selected questions at various difficulty levels.

"If you only have 38 questions," Ms. Fink said, "you can't cover everything."

Treatment in NAEP

While most states included only a few test items about evolution, that treatment is similar to the approach used on one of the most heavily scrutinized precollegiate tests in the country, the National Assessment of Educational Progress. On the 2005 version of the science NAEP, 12th graders were quizzed about four items that referred specifically to evolution and five others that covered related concepts, making up 4 percent of the 209 total questions.

NAEP also provides a glimpse of how well students performed when questioned about evolution. Fifty-one percent of the 12th graders picked the correct answer on a multiple-choice question from 2000 about different aspects of the concept. *(See box, this page.)*

By comparison, 61 percent correctly answered a question about sexual and asexual reproduction in animals.

In Utah, a state that reported having about 15 evolution-related items on its high school exam, 61 percent and 66 percent of students reached the "proficient" level on two different parts of the state biology test most directly related to evolution, while 67 percent who scored proficient on the overall exam. Students there are required to take at least two high school science tests; the biology exam is one option.

Utah officials have no inclination to include questions about intelligent design or other alternative views on their exam. "Those things don't belong in science," said Brett Moulding, the state's director of curriculum.

Top-Down Mandates

Several experts on science education and testing said they fully expected that states were not testing students on views critical of evolution. They noted that precollegiate science teachers, who generally want evolution taught, often play a major role in shaping the content of tests.

"For the vast majority of biology teachers out there, there's no controversy here. There's no close call," said Bruce A. Fuchs, the director of the office of education at the National Institutes of Health, an arm of the federal government. He speculated that any future efforts to promote alternatives to evolution in science testing were "likely to be forced in from the top," if at all, "rather than coming from teachers."

Treatment of Evolution Inconsistent

BY SEAN CAVANAGH

State standards for academic content vary enormously in how well they cover the topic of evolution, with many of those documents either ignoring or giving scant treatment to the core principles of that established scientific theory, an *Education Week* analysis shows.

Nearly all the science standards reviewed at least mention the theory advanced most famously by Charles Darwin, as well as the related concept of natural selection. But many of those standards, the basic documents describing what students are expected to know, fail to address the fundamental evidence supporting the theory, which explains how life on Earth developed.

Many states' standards, for instance, make little or no connection between the theory of evolution and established scientific evidence about the age of the Earth, internal similarities between organisms, or the common ancestry of different species.

The findings emerge as the theory of evolution faces attacks in states and school districts across the country. Meanwhile, a closely watched federal trial on purported alternatives to its teaching is coming to an end in Harrisburg, Pa.

Education Week reviewed the science standards of a large majority of the states, comparing them against 10 concept statements about evolution in the National Science Education Standards, or NSES. That document, published by the congressionally chartered National Research Council in 1996, is widely regarded as a prime reference tool for what students should know about science. The review was conducted jointly with the Education Week Research Center, with the help of an independent computer database maintained by a nonprofit research organization called Align to Achieve. That database included complete versions of science standards from 41 states.

The review found that the vast majority of those state documents, or 39, offer some description of biological evolution and how it accounts for the diversity of species that exist today. Nearly as many of those standards, 35, give similar treatment to natural selection, Darwin's principle that species evolve through the passing on of advantageous traits to their offspring. Overall, at least 25 states met at least half the 10 NSES concept statements for student understanding of evolution.

Yet state standards are less successful in addressing other important evolutionary principles, the analysis found. Fewer than half the states reviewed, or 20, describe the way that the internal structures and chemical processes of organisms provide evidence of their common ancestry.

Only 21 states describe how random mutation or other changes in DNA and cells can affect evolution, and just 22 describe how the various mechanisms of evolution work. And only six states describe how long evolution has been producing diversity in organisms—through at least 3.5 billion years of the Earth's history, most scientists say.

"I'm not impressed," Wayne W. Carley, the executive director of the National Association of Biology Teachers, in Reston, Va., said of the results. "Evolution is the cornerstone and the building block of modern biology. It should be the centerpiece of modern biology education."

Uneven Record

State standards play an influential role in shaping what students are taught in public schools. In many cases, the standards determine what questions students will encounter on standardized tests. They also shape the content of science textbooks, which publishers typically have written to align with the standards of the largest states.

Several states have augmented their science standards with reams of curricular materials and supplementary documents, which have provided more detailed descriptions of evolution and many other scientific concepts.

Some state officials contend that those secondary materials set more rigorous expectations for teachers and students than the standards themselves, which are aimed at providing relatively broad learning goals. Still, secondary curricular documents tend to receive much less public scrutiny than the actual standards. And in some cases, the secondary materials have not been subjected to a potentially exhaustive review by state school boards, legislatures, or other public entities.

"Standards represent a public consensus," said Gerald Skoog, a retired education professor at Texas Tech University in Lubbock. Mr. Skoog is the former president of the National Science Teachers Association, and has studied science standards extensively. "They've gone through a political process."

For decades, questions about evolution's status in public school science classrooms have sprung up sporadically, but the issue has roiled states and districts anew in recent months. Many officials and residents are pushing to have students told of supposed weaknesses in the theory. The 3,600-student district in Dover, Pa., for instance, has sought to inform students of ideas such as "intelligent design" in addition to evolution, a policy that is now the subject of an ongoing federal lawsuit being heard in Harrisburg.

> *Evolution is the cornerstone and the building block of modern biology. It should be the centerpiece of modern biology education*
>
> **Wayne W. Carley**
> *Executive Director*
> *National Association of Biology Teachers*

Both sides concluded their arguments last week in that heavily scrutinized case. *(See Education Week, Oct. 20, 2005.)*

Intelligent design is the idea that an unidentified force may have guided various aspects of life's development, which proponents argue is too complex to have arisen otherwise. The vast majority of scientists, however, reject intelligent design as an essentially religious and scientifically unverifiable belief, and say that evolution is, in fact, one of the most thoroughly tested explanations in science. Evolution posits that species develop over time, through natural selection and random mutation.

State standards, meanwhile, have grown increasingly important under the mandates of the federal No Child Left Behind Act. The nearly 4-year-old law requires states to have science standards in place by the end of this school year, and to begin testing students annually in that subject at three different grade spans—3-5, 6-9, and 10-12—by the end of 2007-08.

The NSES concepts selected by *Education Week* for its analysis were closely aligned with Benchmarks for Science Literacy, another widely respected set of standards, published in 1993 by the American Association for the Advancement of Science, or AAAS. Several states list one or both of those documents as having guided the development of their standards. States did not need to match the NSES wording exactly, or even approximately, to score well in the analysis; they needed only to address various concepts in general terms and connect them with evolution.

The analysis was completed by using a national database of standards created by Align to Achieve, an organization based in Cambridge, Mass., that conducts research on standards in various content areas. The review focused on 41 states with standards housed in Align to Achieve's database.

That database includes only state-accepted standards—typically, documents that were approved by a state board of education or legislature—rather than supplementary materials. State standards are in near-constant flux, and some of the standards in the database have since been replaced by more recent versions.

One Word Missing

In its review, *Education Week* found four states—Florida, Illinois, Kentucky, and Oklahoma—that do not mention the term "evolution," as it pertains to biological changes in species, anywhere in the body of their science standards.

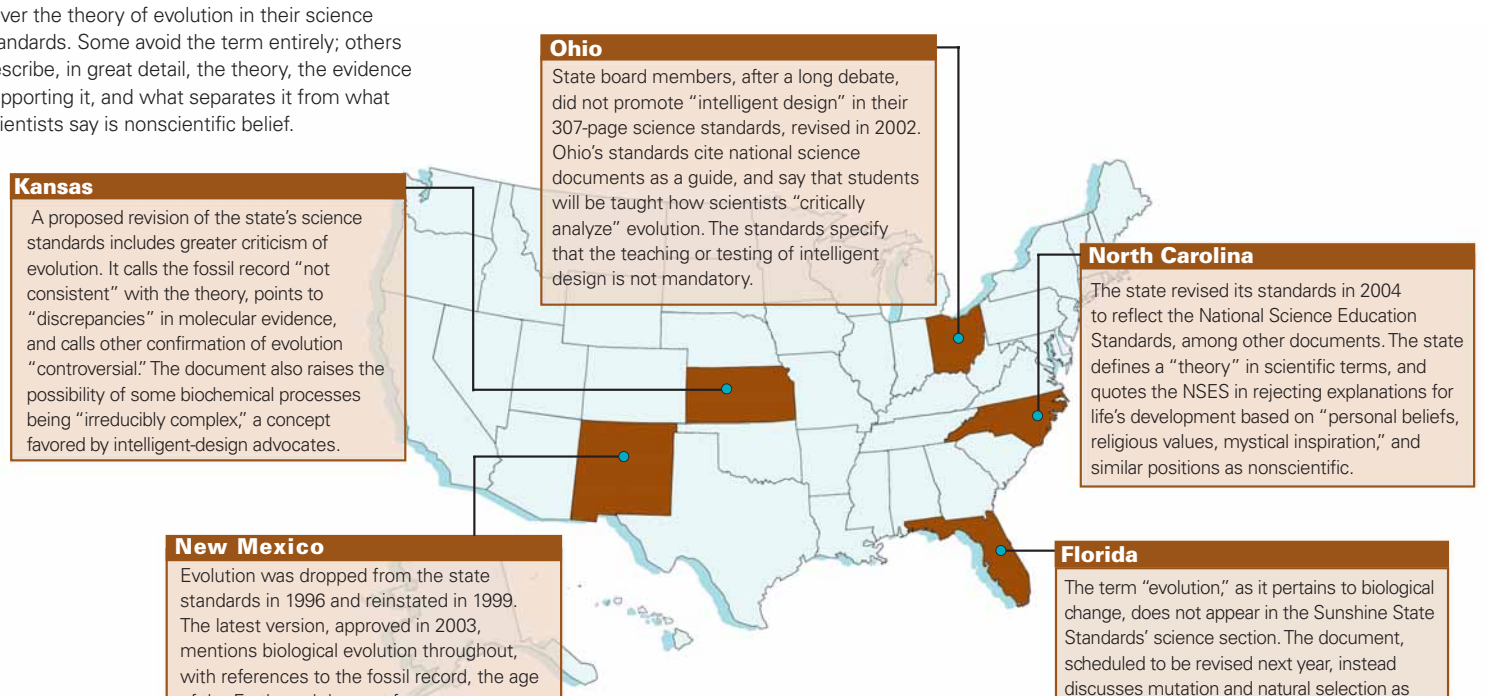
The Illinois Learning Standards for Science scored poorly in the analysis. Without employing the term "evolution," they specify that students should be able to "describe processes by which organisms change over time," using evidence from the fossil record and other sources. The other three states use similar substitute language.

Gwen Pollock, the principal state science education coordinator in Illinois, said that despite omitting the term from the standards, state officials in no way were suggesting that students shouldn't master the concept.

She also noted that Illinois officials have produced separate documents, known as "performance descriptors," that do mention evolution specifically. Those documents are meant to provide

Mapping Evolution

States vary enormously in how thoroughly they cover the theory of evolution in their science standards. Some avoid the term entirely; others describe, in great detail, the theory, the evidence supporting it, and what separates it from what scientists say is nonscientific belief.



Ohio
State board members, after a long debate, did not promote "intelligent design" in their 307-page science standards, revised in 2002. Ohio's standards cite national science documents as a guide, and say that students will be taught how scientists "critically analyze" evolution. The standards specify that the teaching or testing of intelligent design is not mandatory.

Kansas
A proposed revision of the state's science standards includes greater criticism of evolution. It calls the fossil record "not consistent" with the theory, points to "discrepancies" in molecular evidence, and calls other confirmation of evolution "controversial." The document also raises the possibility of some biochemical processes being "irreducibly complex," a concept favored by intelligent-design advocates.

North Carolina
The state revised its standards in 2004 to reflect the National Science Education Standards, among other documents. The state defines a "theory" in scientific terms, and quotes the NSES in rejecting explanations for life's development based on "personal beliefs, religious values, mystical inspiration," and similar positions as nonscientific.

New Mexico
Evolution was dropped from the state standards in 1996 and reinstated in 1999. The latest version, approved in 2003, mentions biological evolution throughout, with references to the fossil record, the age of the Earth, and descent from common ancestors. The standards say students should "critically analyze" data supporting evolution.

Florida
The term "evolution," as it pertains to biological change, does not appear in the Sunshine State Standards' science section. The document, scheduled to be revised next year, instead discusses mutation and natural selection as "mechanisms of change" that can produce "adaptations in a species."

SOURCE: *Education Week*

teachers and students with more detail about the material they will face on statewide assessments, Ms. Pollock said.

"There is accountability through the statewide assessment," she said, adding that Illinois officials were "very confident" that students were learning about evolution.

Science Content Weak?

Education Week's findings echo some of the conclusions of earlier studies of state standards and evolution. A 2000 study by the Washington-based Thomas B. Fordham Foundation found that roughly two-thirds of states did at least a satisfactory job of explaining evolution in their standards, but that individual states' performance ranged from "excellent" to "disgraceful."

Paul R. Gross, a professor emeritus of life sciences at the University of Virginia in Charlottesville, is leading a new Fordham study of state science standards, to be released soon, which includes a look at evolution language. He said his research was indicating that most state standards treated evolution "reasonably well," though their quality varied greatly.

Mr. Gross also suggested that singling out evolution as a weak spot in state standards is misleading, because those documents lack academic depth across many areas.

"The handling of evolution is disappointing," he said, "but the handling of science content overall is disappointing."

Other states besides Illinois are also relying on secondary documents to describe evolution in greater detail than in the state standards themselves. Wisconsin's Model Academic Standards for Science Instruction didn't fare well in *Education Week*'s analysis, with descriptions of evolution that failed to provide detail comparable with the NSES concepts.

But Wisconsin officials are writing a new "assessment framework" that will describe evolution and other concepts in greater detail, said Shelley A. Lee, the state's science education consultant. Wisconsin has also issued a statement describing evolution as a "fundamental and important" concept in science and has warned that attempts to teach religious belief in science class are illegal.

"You really have to look beyond the standards," Ms. Lee said. She said she regularly points teachers and parents to the framework "for even greater specificity and clarity."

Kentucky, which makes no mention of the term evolution in its standards, also scored poorly in *Education Week*'s overall analysis of coverage of the theory. State officials believe their standards should have fared better, arguing that the document clearly expects students to understand evolutionary concepts, even if the term isn't mentioned. They also note that an additional guide for teachers and others, known as the "core content for assessment," is being revised to include the term itself.

"It's obvious to me—we support the teaching of evolution," said Lisa Gross, a spokeswoman for the Kentucky education department. Including the specific term, she maintained, is less crucial than "teaching students how to learn."

But Jo Ellen Roseman, the director of Project 2061, a longstanding enterprise at the AAAS to promote literacy in science, mathematics, and technology, dismissed efforts to describe evolution while dodging the term itself.

"'Change over time'—that's not evolution," Ms. Roseman said. "We expect that students who graduate from high school will be able to read the term 'evolution' in the newspaper and know what it is."

Glenn Branch, the deputy director of the National Center for Science Education, an Oakland, Calif., organization that opposes the teaching of intelligent design and creationism in science classes, agreed.

"It conveys the idea that there's something menacing in the e-word," Mr. Branch said of omitting the term. "It doesn't do students a service to not use standard scientific terminology."

Besides setting clear expectations for students, he added, standards serve another function: They are authoritative state documents teachers can rely on when confronted with outside pressure to teach creationism or intelligent design.

"Teachers who face irate parents can point to the state standards," Mr. Branch said.

'Secondary Battleground'

Several state officials explained the lack of detail about evolutionary theory by saying that standards should provide relatively broad learning goals for students—and secondary documents, more detailed language.

"State standards are more global statements," said Dixie Stack, the director of curriculum in Maryland, which did relatively well in the analysis. Her state also offers a more detailed treatment of evolution in a curriculum document outside of the state standards. "We develop curriculum for teachers to know what students are expected to know about those global statements," she said.

Mr. Carley of the biology teachers' association, said that approach could work. "There are multiple layers at which evolution can expand or contract," he said. "As long as it expands, that's OK."

But Mr. Branch of the center for science education warned that such supplementary documents were beginning to emerge as a "secondary battleground" in debates over evolution. Ohio's state board of education, after a prolonged debate, approved revised science standards in 2002 that do not advocate intelligent design. That document is "not bad" in its overall treatment of evolution, Mr. Branch argued, and it scored well in *Education Week*'s overall analysis.

Yet after the furor subsided, Ohio officials in 2004 approved an additional science lesson plan titled "Critical Analysis of Evolution." That document drew objections from many state and national science organizations.

One state that scored well in *Education Week*'s review, Rhode Island, relied extensively on the AAAS science standards in crafting its document. Closely following that model gave educators and others the detail they needed to shape classroom lessons, said Linda A. Jzyk, a science and technology specialist for the state.

"The more specificity we can provide, the better for all," she said. "It helps the teacher in their daily practices, [and] it helps districts in shaping their curriculum."

Evolution Concepts

An *Education Week* review shows that state science standards are uneven in their treatment of evolution. The analysis looked at how well 41 states covered 10 concepts related to evolution identified in the 1996 National Science Education Standards.

General Concept	NSES Language	States With Matching Content (out of 41)
Biological adaptation and survival	Biological evolution accounts for the diversity of species developed through gradual processes over many generations. Species acquire many of their unique characteristics through biological adaptation, which involves the selection of naturally occurring variations in populations. Biological adaptations include changes in structures, behaviors, or physiology that enhance survival and reproductive success in a particular environment.	39
Natural selection	Like other aspects of an organism's biology, behaviors have evolved through natural selection. Behaviors often have an adaptive logic when viewed in terms of evolutionary principles.	35
Fossil record reflects changing life forms	Fossils indicate that many organisms that lived long ago are extinct. Extinction of species is common; most of the species that have lived on the Earth no longer exist.	34
Environmental changes affect survival	Extinction of a species occurs when the environment changes and the adaptive characteristics of a species are insufficient to allow its survival.	32
Similarity among diverse species	Natural selection and its evolutionary consequences provide a scientific explanation for the fossil record of ancient life forms, as well as for the striking molecular similarities observed among the diverse species of living organisms.	27
Mechanisms of evolution	Species evolve over time. Evolution is the consequence of the interactions of (1) the potential for a species to increase its numbers; (2) the genetic variability of offspring due to mutation and recombination of genes; (3) a finite supply of the resources required for life; and (4) the ensuing selection by the environment of those offspring better able to survive and leave offspring.	22
Classification systems reflect evolutionary relationships	Biological classifications are based on how organisms are related. Organisms are classified into a hierarchy of groups and subgroups based on similarities which reflect their evolutionary relationships. Species is the most fundamental unit of classification.	22
Variable effects of genetic change	Changes in DNA (mutations) occur spontaneously at low rates. Some of these changes make no difference to the organism, whereas others can change cells and organisms. Only mutations in germ cells can create the variation that changes an organism's offspring.	21
Common ancestry of species	Millions of species of animals, plants, and microorganisms are alive today. Although different species might look dissimilar, the unity among organisms becomes apparent from an analysis of internal structures, the similarity of their chemical processes, and the evidence of common ancestry.	20
Time frame of biological evolution	The great diversity of organisms is the result of more than 3.5 billion years of evolution that has filled every available niche with life forms.	6

Evolution in State Science Education Standards

Research Brief

Christopher B. Swanson

November 2005

Science, Education, and Evolution

A large majority of scientists view the theory of biological evolution as accepted knowledge that has firmly withstood generations of empirical scrutiny and analysis. The core tenets of the theory are considered beyond serious dispute and represent a bedrock upon which the architecture of the modern life sciences have been built. Although a largely settled issue within scientific circles, encounters between evolution and the general public, politics, and the educational establishment in the United States have often been unsettling.

Starting most prominently with the fabled Scopes trial in 1925, critics of the theory have repeatedly opposed the teaching of evolution in the public schools. In a more contemporary example of such a challenge, between 1999 and 2001, the Kansas state board of education removed (and subsequently reinstated) references to biological evolution from the state's academic standards. In 2002, Ohio inserted language into its academic standards that effectively contests the scientific standing of evolution by calling on students to "describe how scientists continue to investigate and critically analyze aspects of evolutionary theory."

That passage from Ohio's standards is immediately qualified by a disclaimer noting that the preceding statement does not constitute a mandate to either teach or test on "intelligent design." This alternative explanation contends that certain biological processes and structures are so complex that they could not be a product of the mechanisms delineated by the theory of evolution. Intelligent design instead proposes that the development of life on Earth bears the mark of an outside designer or pre-existing intelligence. This counter explanation has gained currency among critics of evolution in recent years and lies at the heart of a federal trial currently under way in Harrisburg, Pa. In that proceeding, parents from the nearby town of Dover are seeking to overturn a school district policy that requires high school students to be introduced to the concept of intelligent design in addition to evolutionary theory.

Two approaching milestones in the federal No Child Left Behind Act related to science education have increasingly occupied the attention of the education and policy communities. Under the federal law, all states are required to have science education standards in place by the end of the 2005-06 school year. By the 2007-08 school year, states must also initiate annual assessments in science at the elementary, middle, and high school levels. In light of these developments, the academic content identified by states as core scientific knowledge for students to learn will soon carry even greater importance for the nation's schools.

This report describes the results of a systematic analysis of state science education standards conducted by the Editorial Projects in Education Research Center in conjunction with *Education Week*. We obtained information on the science education standards in 41 states from an extensive electronic database and devised a rigorous study methodology for analyzing the evolution content of those standards. In so doing, we were able to determine the extent to which the science standards in each state aligned with the treatment of evolutionary theory outlined in one influential and widely respected national standards document – *National Science Education Standards*, published by the National Research Council in 1996.

Our findings show that all of these state offer at least some minimal amount of attention to the theory of evolution or its attendant concepts, despite the fact that several states do not explicitly mention the word "evolution" in their standards. As described in detail below, considerable variation can be found in the extent to which different state standards capture key concepts related to evolution. Similarly, while certain basic aspects of evolution are covered by nearly all of these states, markedly fewer states' standards include statements pertaining to more subtle or potentially controversial elements of the theory.

Methodology

In this study, we perform a systematic and objective analysis of state academic standards in science education in order to characterize the extent to which these documents cover the theory of biological evolution. Studies of this kind typically adopt one of two general methodological approaches.

Some reviews of academic standards, for example, rely on an expert-driven process. Under this model, an individual reviewer (or team) with expertise in a particular content-knowledge area first develops a set of review criteria delineating concepts or features of interest. This rubric is then used to evaluate a series of standards documents in order to generate a score or grade for each set of standards. Expert-driven reviews of academic standards can provide very useful insights into the nature of content-knowledge expectations. If not carefully implemented, however, the results of such investigations can be swayed by the biases of the reviewers. The potential for bias can be minimized by taking such steps as providing explicit statements describing the study's conceptual orientation and its analytic rubrics or using multiple reviewers. When employing the latter measure, the issue of inter-rater reliability should also be taken into consideration.

In the present study, we have pursued an alternative approach to analyzing academic standards that might be described as a benchmarking strategy. This methodology starts by identifying an existing statement of academic content knowledge. This external standard then becomes a benchmark against which other sets of standards are compared. The objective here is to determine how closely a given set of standards aligns with the content of another particular document that serves as the benchmark. These types of studies are heavily reliant on the validity of the standards selected as the point of reference. Disputed or controversial benchmarks could call into question the results of such an investigation. For the present study, we have adopted the National Research Council's *National Science Education Standards* (*NSES*) as our objective benchmark. Highly respected within both scientific and educational communities, the *NSES* document outlines a vision of scientific literacy and includes standards describing what students should know and be able to do at particular grade levels.

From the *NSES*, we derive a set of concept statements describing core evolutionary principles. These benchmark concepts are then compared with the content of state-adopted academic standards in order to determine the extent to which the content in the states' standards aligns with the treatment of biological evolution in the *NSES*. As the following step-by-step description of the study methodology indicates, we utilize an extensive electronic database of academic standards and a standardized set of procedures and decision rules. These measures help to minimize the possibility that subjective judgments will affect the results of the analyses, thereby strengthening confidence in the findings.

Step 1:
Identifying Evolution Benchmark Concepts

Published in 1996, the *NSES* is a highly regarded and widely-cited statement of the content knowledge that students should be expected to learn in K-12 science education. In fact, a number of states have looked to this document as a model when developing their own academic standards in science. In consultation with outside experts in science and science education, we identified 10 statements from *NSES* that describe core concepts related to the theory of biological evolution. These statements, listed in Exhibit 1, span an array of topics that many experts would consider to reflect essential knowledge about evolution.

A potential critique that might be offered of this study lies in the choice of *NSES* as a point of reference for our analysis. For instance, it might be argued that another set of reference standards could have generated a different set of core evolution concepts and, therefore, different analytic results. Cognizant of this possibility, we also examined the treatment of evolution found in *Benchmarks for Science Literacy*, published by the American Association for the Advancement of Science (AAAS) in 1993. Like *NSES*, the AAAS document enjoys a strong reputation and has also been used as a guide in the development of state science standards. We found very close correspondence between the coverage of evolutionary theory in both *NSES* and *Benchmarks*. In fact, all 10 of the core evolution concepts from *NSES* examined in this study also appear in the AAAS document. This finding suggests that the results of our analysis are not unduly dependent on the choice of *NSES* as our benchmark, which provides validation for the methodology used in this study.

Step 2:
Linking Evolution Concepts to the Standards Database

The systematic analysis of evolution-content coverage performed in this study is made possible by an extensive database of academic standards documents maintained by Align to Achieve Inc. (A2A). This Standards Database comprehensively catalogs the content of science standards documents created by the states, the National Research

What is A2A? Align to Achieve, Inc., is an independent, not-for-profit organization created in October of 2001 as an outgrowth of its parent company, Achieve, Inc. One of the main purposes of Align to Achieve (A2A) is to build and maintain a Standards Database of the latest K-12 content standards and benchmarks from states, national organizations, and selected countries. For more information: www.aligntoachieve.org

EXHIBIT 1: EVOLUTION CONCEPTS FROM *NSES*

Evolution Concept Label	A2A Triplet Code	*NSES* Benchmark Language
Common ancestry of species	**4.3.4**	Millions of species of animals, plants, and microorganisms are alive today. Although different species might look dissimilar, the unity among organisms becomes apparent from an analysis of internal structures, the similarity of their chemical processes, and the evidence of common ancestry.
Classification systems reflect evolutionary relationships	**4.4.1**	Biological classifications are based on how organisms are related. Organisms are classified into a hierarchy of groups and subgroups based on similarities which reflect their evolutionary relationships. Species is the most fundamental unit of classification.
Variable effects of genetic change	**5.4.4**	Changes in DNA (mutations) occur spontaneously at low rates. Some of these changes make no difference to the organism, whereas others can change cells and organisms. Only mutations in germ cells can create the variation that changes an organism's offspring.
Fossil record reflects changing life forms	**9.3.1**	Fossils indicate that many organisms that lived long ago are extinct. Extinction of species is common; most of the species that have lived on the earth no longer exist.
Biological adaptation and survival	**9.3.2**	Biological evolution accounts for the diversity of species developed through gradual processes over many generations. Species acquire many of their unique characteristics through biological adaptation, which involves the selection of naturally occurring variations in populations. Biological adaptations include changes in structures, behaviors, or physiology that enhance survival and reproductive success in a particular environment.
Changes in the environment	**9.3.3**	Extinction of a species occurs when the environment changes and the adaptive characteristics of a species are insufficient to allow its survival.
Natural selection	**9.4.2**	Like other aspects of an organism's biology, behaviors have evolved through natural selection. Behaviors often have an adaptive logic when viewed in terms of evolutionary principles.
Similarity among diverse species	**9.4.3**	Natural selection and its evolutionary consequences provide a scientific explanation for the fossil record of ancient life forms, as well as for the striking molecular similarities observed among the diverse species of living organisms.
Mechanisms of evolution	**9.4.4**	Species evolve over time. Evolution is the consequence of the interactions of (1) the potential for a species to increase its numbers, (2) the genetic variability of offspring due to mutation and recombination of genes, (3) a finite supply of the resources required for life, and (4) the ensuing selection by the environment of those offspring better able to survive and leave offspring.
Timeframe of biological evolution	**9.4.5**	The great diversity of organisms is the result of more than 3.5 billion years of evolution that has filled every available niche with life forms.

Council (i.e., *NSES*), and several other professional organizations (e.g., AAAS). Every set of standards contained in the database has been divided into numerous (typically several hundred) individual entries, each of which contains a discrete standard, benchmark, or statement of scientific-content knowledge. Some state standards present content knowledge in outline form while others describe this content using more extended passages of prose. So depending on the ways in which a particular standards documents is organized, database entries can range in length from a short phrase to an entire paragraph.

Entries in the A2A database are organized using a heuristic tool known as the "Compendix," an extensive index of distinct scientific concepts, each of which is identified by a unique three-part code known as a "triplet." The triplet system of the Compendix catalogs scientific concepts in much the same way as the Dewey Decimal system would be used to catalog holdings in a library collection. In addition to its focal statement of academic-content knowledge, each Compendix entry also provides a set of vocabulary terms related to that particular concept.

When benchmark statements derived from a standards document (e.g. *NSES* or a state's academic standards) are added to the Standards Database, each entry is assigned a triplet code that refers to the corresponding scientific concept from the Compendix. The state benchmark is also indexed

using a subset of relevant concept vocabulary terms. A database entry might be indexed against more than one Compendix triplet code if the standard statement captures multiple concepts (a common occurrence with longer entries). For the purposes of illustration, Exhibit 2 depicts an A2A database entry from *NSES* related to evolution. The first portion of the entry contains the content of the benchmark statement as it appears in the *NSES* document. The second part of the entry describes the Compendix benchmark that corresponds to this evolution principle (including the triplet key, Compendix text, and related concept vocabulary).

As the description above suggests, the Compendix is the common language of the A2A database and the device used to systematically catalog the multitude of entries from state and professional standards documents. The triplet codes can also be used to perform a crosswalk. That is, we can align the content captured across multiple sets of standards by means of their shared triplet codes. The first step in this crosswalk process involves identifying the Compendix triplet codes assigned to the 10 *NSES* concept statements on evolution. This was accomplished using the publicly accessible database search on the Align to Achieve Web site. For reference purposes, Exhibit 1 above lists the triplet codes corresponding to the focal evolution concepts. Using these triplets, we can proceed with the two-stage electronic search process that will enable us to identify the state standards or benchmarks corresponding to these evolution concepts from *NSES*.

EXHIBIT 2: SAMPLE A2A DATABASE ENTRY

National Science Education Standards (NSES) Grade: 9 - 12 Science

Life Science
Content Standard C:
As a result of their activities in grades 9-12, all students should develop understanding of
- The cell
- Molecular basis of heredity
- Biological evolution
- Interdependence of organisms
- Matter, energy, and organization in living systems
- Behavior of organisms

Biological Evolution

Natural selection and its evolutionary consequences provide a scientific explanation for the fossil record of ancient life forms, as well as for the striking molecular similarities observed among the diverse species of living organisms.

Achieve+McREL Standards Catalog Alignment

Subject	Benchmark Key	Benchmark with Concept Vocabulary
Science	9.4.3	Knows how natural selection and its evolutionary consequences provide a scientific explanation for the diversity and unity of past and present life forms on Earth (e.g., recurring patterns of relationship exist throughout the fossil record; molecular similarities exist among the diverse species of living organisms; the millions of different species living today appear to be related by descent from common ancestors) A. natural selection, B. biological evolution, E. prehistoric life forms, G. fossil record, H. species similarity, I. organism, M. molecular similarity

Step 3:
Triplet Search of the A2A Database

As mentioned previously, the A2A Standards Database systematically catalogs academic standards that have been adopted by the states or published by professional organizations in four core-subject areas. It should be noted that the database does not contain draft versions of state standards or supplementary documents such as curricular guides that have not been officially adopted as standards by the appropriate state authority (e.g., board of education or legislature). At present, the database houses K-12 science education standards from 41 states, in addition to *NSES* and the AAAS *Benchmarks* documents.

State academic standards themselves are in a nearly constant state of evolution, with revised documents periodically adopted to replace earlier versions. This reality of the standards-development and -adoption process has two implications for the present study. First, there are several instances where the A2A database contains multiple documents for a given state, representing different revisions of the standards adopted at different points in time. When such a situation was encountered, we selected the more recent version of the standards for analysis. Second, it is possible that the science standards available for a given state in the A2A database could have been superseded by a more recent version. In light of approaching No Child Left Behind mandates, it is also reasonable to anticipate a major wave of state revisions and adoptions for science standards in the near future.

Although keeping up-to-date in a rapidly changing field can be extraordinarily difficult, we can at least provide the reader with additional information about the standards documents analyzed for this study. Exhibit 3 lists the title of each of these standards documents, along with the year in which those standards were adopted by the state.

Wyoming	2003	Wyoming Science Content and Performance Standards

Align to Achieve offers a variety of online-search functions that can be utilized to explore the standards database. Two separate search processes were employed in the present study.

In the first stage, we performed an electronic search to identify state standard entries that were assigned one of the Compendix triplets corresponding to the 10 core evolution concepts from *NSES*. So in effect, 410 separate queries were performed – one for each of the 10 triplet codes in each of the 41 states with standards in the A2A database. To facilitate this process, Align to Achieve provided the researchers with access to an administrative database.

For a given state and triplet, this query could generate multiple "hits" (cataloged statements indexed against the triplet), one hit, or no hits. It should be noted that the indexing of entries in the A2A database by triplet codes is concept-dependent, not vocabulary-dependent. So a state need not use the same terminology as *NSES* (or the Compendix) to describe a particular evolution concept in order to generate a hit in this search.

Step 4:
Keyword Search of the A2A Database

The A2A Standards Database was constructed by analysts who reviewed state (and other) standards documents, subdivided these documents into discrete benchmark-sized entries, and indexed each entry using one or more Compendix triplet codes and a set of concept vocabulary terms. Particularly when entries contain compound statements capturing multiple closely-related concepts, the matter of indexing a particular entry may not be entirely straightforward. In order to accommodate any possible ambiguity that might have arisen in the indexing of standards as the database was being compiled, we performed a secondary search to complement the triplet-based search described above.

This second query involved a keyword search of the A2A database. For each of the 10 focal evolution concepts, we identified from one to three key terms or phrases related to that particular aspect of evolutionary theory. Exhibit 4 lists these keyword search terms, with the underlined portion of the term representing the exact search string used. Like the initial triplet search, this procedure generated a set of hits – state benchmarks containing the relevant keyword term. The hits from the two search stages were then pooled together for further examination in the final stage of our analysis.

Step 5:
Vetting "Hits" from Electronic Searches to Identify "Matches"

Mechanistic search processes, such as those described above, are useful to the extent that they provide a way to conduct an automated, systematic query. However, such searches are also necessarily limited by the functional parameters of the search engine and the organization of the underlying database. As a result, it is possible – often inevitable – that some false hits will be generated. For instance, the Compendix index that organizes the A2A Standards Database often consists of statements that are more extensive than those appearing in the *NSES* or state benchmark entries. A Compendix statement related to evolution could, therefore, be cataloged according to multiple elements or subconcepts. Not all of these subconcepts will be relevant for our analysis.

Consequently, it is necessary to vet each individual hit from the electronic searches in order to determine whether it matches the evolution concept actually being targeted. A vetting rule or guideline was developed and applied for each of the 10 focal evolution concepts. These rules (reported in Exhibit 4) provide a transparent and uniform method for determining whether a mechanical "hit" generated by our search actually constitutes a "match" in terms of the content of the statement.

Summary of Findings

Using the methodology described above, we performed an alignment analysis focusing on the evolution content of science education standards. That is, we determined the extent to which the science standards of a particular state captured the 10 core evolution concepts derived from *NSES*.

Exhibit 4: Search and Vetting Criteria

Evolution Concept Label	A2A Triplet	Keyword Search Terms	Vetting Guidelines
Common ancestry of species	**4.3.4**	evolutionary relationship common ancestry kinship	Benchmark notes common ancestry or evolutionary relationships among species (which may display surface dissimilarities).
Classification systems reflect evolutionary relationships	**4.4.1**	classification evolutionary relationship	Benchmark makes connection between biological classification systems and the evolutionary relationships among species. Link to classification can also be described in terms of degree of kinship, common descent, or common ancestry of species.
Variable effects of genetic change	**5.4.4**	value of characteristic mutation genetic change	Benchmark describes that genetic changes can have variable effects that relate to organism or species success.
Fossil record reflects changing life forms	**9.3.1**	fossil	Benchmark references the fossil record and changes in life forms over time (e.g., extinction, emergence of new species, or diversification of life).
Biological adaptation and survival	**9.3.2**	biological adaptation survival	Benchmark cites biological adaptation or survival. Benchmark does not need to mention evolution explicitly to receive credit.
Changes in environment	**9.3.3**	extinction environment survival	Benchmark relates changes in the environment to the process of extinction, survival, or adaptation.
Natural selection	**9.4.2**	natural selection	Benchmark references or describes natural selection. Credit for match awarded even for brief reference or citation of term "natural selection."
Similarity among diverse species	**9.4.3**	diversity similarity common descent	Benchmark establishes clear connection between evolution and similarities among species.
Mechanisms of evolution	**9.4.4**	natural selection	Benchmark explicitly elaborates on the theory of evolution by citing or describing relevant mechanisms related to natural selection (e.g., environmental pressures, variation within species, adaptation, survival). At least one such mechanism must be cited. Credit not awarded for simply citing the term "natural selection."
Timeframe of biological evolution	**9.4.5**	billion	Benchmark explicitly describes the time of the evolution of life forms as occurring over billions of years.

A detailed state-by-concept table presenting the results of our analysis appears in Exhibit 5. States are ranked by alignment score, indicating the number of *NSES*-derived evolution concepts covered in their respective standards.

We find that all of the 41 state standards examined in this analysis contain some content related to the theory of biological evolution. That is, each set of state standards contains language that aligns with at least one of the focal evolution concepts. Based on these results, we can conclude that none of these states completely excludes the topic of evolution from their standards. However, despite the fact that most experts consider evolution theory to be an essential element of science education, our findings reveal a

tremendous range in the extent of coverage that the various state standards afford to this topic.

No state scored a zero. However, the number of concepts reflected in the state standards ranges from a low of one to a high of 10. In the two states at the low end of the spectrum (New York, North Dakota), for example, coverage of evolution is limited to a single topic – the process of biological adaptation as it pertains to the survival of organisms and reproductive success. Another pair of states score matches for only two concepts. Standards in Kentucky likewise address the subject of adaptation, along with fossil-record evidence for evolution. In Montana, standards reference natural selection and the evolutionary relationships that underlie biological-classification systems.

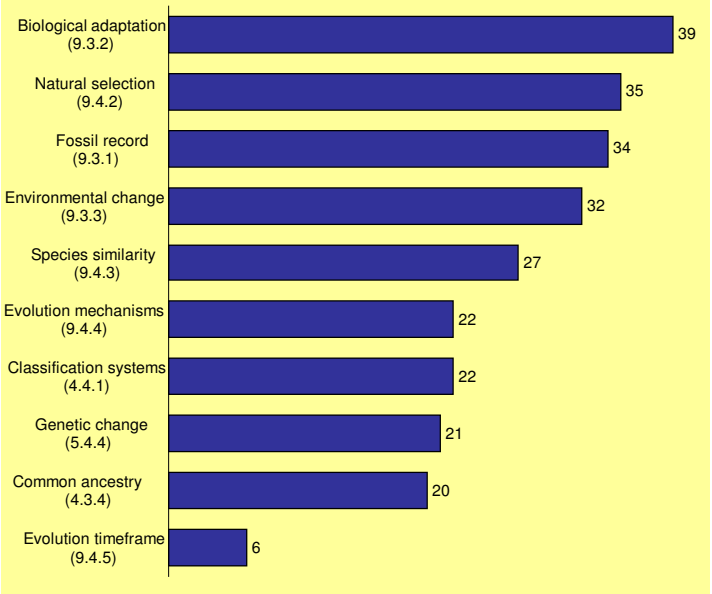
At the opposite end of the scale, a "perfect" alignment score was received by four states – Arizona, Indiana, New Mexico, and Ohio. The science standards in these states capture all 10 of the focal evolutionary concepts. Most states, of course, fall somewhere between these extremes. In the average state, science education standards cover just over half (six) of the core topics identified from the *NSES*.

The particular combination of concepts covered by the states displays some variation, even among those receiving similar scores. An examination of the results reveals some interesting patterns (see Exhibit 6). For instance, some evolution concepts are covered in nearly all states, while others are included in the standards of only a handful of states. Among the evolution concepts examined, the topic of biological adaptation (triplet 9.3.2) was the most frequently encountered, appearing in the science standards of 39 out of 41 states analyzed. Over 30 states also provided some treatment of three other core concepts: natural selection as a key element of evolutionary theory (9.4.2); the fossil record as evidence of changing and evolving life forms (9.3.1); and the connection between environmental changes and the survival of species (9.3.3).

By contrast, fewer than half of the 41 state standards noted that evolution provides a basis for understanding that the common ancestry of different species accounts for their underlying similarities (4.3.4). Only six state science standards documents concretely describe the timeframe over which life forms have been shaped by evolution, a period of roughly 3.5 billion years. It should be added that some states offered vaguer references to evolution occurring over a "long" period of time, which our analysis did not credit as a match with the *NSES* standard. These latter findings are noteworthy because the age of the Earth and the length of time life has existed have been points of contention between proponents of evolutionary theory and "young earth" creationists. The latter adhere to a literal interpretation of the Bible, which would place the age of the Earth at about 6,000 years.

A separate keyword analysis was performed to determine whether states use the term "evolution" in the context of describing the biological process of change in organisms and species over time. This particular usage of the term is intended to distinguish statements related to the biological theory of evolution from those describing the history of the universe or geological processes. A number of states also employ the term "evolution" in the latter context. We found that only four states among the 41 analyzed did not mention the word "evolution" (or a related form such as "evolve") in their standards: Florida, Illinois, Kentucky, and Oklahoma. In place of the term "evolution," the standards in these states typically substituted an alternative word or phrase, such as "changes over time," "diversity of species," or "genetic diversity." Two of these states (Florida, Oklahoma) nevertheless received alignment scores in the average range (7 and 5 respectively), despite the fact that their standards do not mention the word "evolution."

Exhibit 6: States With Aligned Benchmark (out of 41)



This finding underscores an important methodological point mentioned earlier. Namely, the procedures used to catalog in the A2A database are not heavily dependent on the use of specific terminology. The critical factor underlying the state alignment scores is simply the representation of the respective evolution concept within the standards documents, in some form or another. In most cases, credit could be earned for having an aligned concept even by a very briefly worded state benchmark, provided that the relevant concept or term was cited in the appropriate context. Therefore, the methodology applied in this study does not inherently discriminate between outline-style standards that consist of short statements (sometimes a single word or phrase) and standards organized around longer passages of text.

CONCLUSION

This study offers one perspective on a critical but complex educational issue. Indeed, the teaching of evolution has often sparked controversy and has repeatedly become entangled in heavily politicized disputes. The current investigation should be viewed as a first step down a fruitful avenue along which researchers can continue to investigate the ways in which the theory of biological evolution has been incorporated in state science education standards. It would be interesting, for example, for analysts to return to this issue again once the states have implemented or revised their science standards as required by the federal NCLB legislation.

The present study has been careful to avoid making normative or qualitative statements about the treatment of evolution in state standards. We have assessed whether or not states address particular intellectual components of evolutionary theory in their standards. But we have offered no speculation as to whether, in a more subjective sense, a particular state's coverage of these topics is either good or bad, adequate or inadequate, exemplary or disgraceful. To an analyst concerned with making such judgments, examples of all of the above could be found among the various state standards.

This observation raises a final issue that is worth mentioning briefly in closing. The alignment score received by a given state's standards in this study does not necessarily reflect a deliberate attempt by the state to deal with the topic of biological evolution in a more or less thorough manner than other scientific principles. Some states have created highly skeletal standards documents in which scientific concepts are essentially listed like vocabulary words. In such cases, no individual issue receives in-depth treatment. By contrast, other states provide substantive explications of the ideas associated with evolution as well as a variety of other central issues in science. So it is important to reiterate that a low alignment score should not be interpreted as an intentional attempt to slight the theory of evolution. Evolution may very well receive equal (if brief) treatment compared with other topics.

There is, however, a broader issue to contemplate in this regard. Namely, one may ask to what extent any set of standards that treats expectations for important scientific knowledge in a highly abbreviated manner can serve as a useful touchstone for the stakeholders in our public schools – the educators who need to develop curricula and instructional strategies, parents who want to know what their children are expected to learn in school, and the public whose well-being in a society that grows more technologically sophisticated by the day will depend on the level of science literacy attained by the next generation.

About Editorial Projects in Education

Editorial Projects in Education (EPE) is a nonprofit, tax-exempt organization based in Washington. Our primary mission is to help raise the level of awareness and understanding among professionals and the public of important issues in American education. We cover local, state, national, and international news and issues from preschool through the 12th grade. Editorial Projects in Education Inc. publishes *Education Week*, American education's newspaper of record, *Teacher Magazine*, EDWEEK.ORG, and Agent K-12. We also produce periodic special reports on issues ranging from technology to textbooks, as well as books of special interest to educators.

The ***EPE Research Center*** conducts annual policy surveys, collects data and performs analyses that appear in the *Quality Counts* and *Technology Counts* annual reports. The center also produces independent research reports and contributes original data and analysis to special coverage in *Education Week*, *Teacher Magazine*, and EDWEEK.ORG.

Christopher B. Swanson, Ph.D., is the director of the Editorial Projects in Education Research Center.
